

Network LAN Design – MIS 4123

Group Eighteen –Joe Yeager – Robert Daigle – John Maye – Andrew Boswell

Current System

Our goal is to replace an aging 10BaseT Ethernet network with a more current Ethernet technology. By migrating to a newer technology we will increase the overall efficiency of the company. The new system will not only include all the requirements needed, but will also leave room for expansion in the future. Our client already has three buildings that each includes a wiring closet. There are 35 PCs and 5 printers that need network access in the Administration Building and 27 PCs and 3 printers in the Engineering Building. We also have to accommodate for the addition 18 PCs and 2 printers in the Manufacturing Building. Our client wants the fastest Ethernet switching technology available and all users need access to the Internet and two centralized servers. We need achieve all these requirements while still keeping also keeping costs down.

Explanation and Justification

After looking over the three layers of the OSI model, we have decided to upgrade the existing network to a system that can hold all the new components asked for by the client. Since our client wants the fastest Internet technology possible, we have decided to put fiber optic cables in between the buildings and going from the switches to the router. We will use UTP Cat 5 cable from the switches to the computers and will also have the switches connected to the server using Ethernet cable. To keep cost down we went with a less expensive server but kept the same backbone which will give the new system upgradable possibilities. We will also install a new router that will connect the new optical fiber to the whole system which also helps increase speed.

OSI Reference Model –Layers

1) The first Layer of the OSI Model is the Physical layer. This layer defines the use of a device and a transmission medium. These types of things include:

- Pins
- Voltages
- Cable Specs.
- Hubs
- Repeaters
- Network Adapters, etc.

The Physical layer would be present in our particular assignment because of the use of cables, switches, routers, and many physical network related things.

2) The second layer of the OSI Model is the Data Link Layer. The Data Link Layer provides the functional and procedural means to transfer data between network entities and to detect and possibly correct errors that may occur in the Physical Layer.

We would need to have this layer present in our system in order to figure out what is wrong with our physical traits, and how the transfer of information is going.

3) The Network Layer, layer 3, provides means for transferring data between networks. It also makes sure that the networks maintain quality of service.

We would not need to use the 3rd layer of OSI because we only have one network in our entire system.

4) The 4th layer of OSI is the Transport Layer. The Transport Layer controls the reliability of a given link through flow control, segmentation/desegmentation, and error control. It provides reliable data transfer between users.

We would use the 4th layer of OSI because we must know how reliable our network is going to be and we also need that reliability to carry over and help our users trust the network.

5) Layer 5 of the OSI Model is the layer that initiates and maintains a connection between application programs on different computers. This layer is called the Session Layer.

We would need to use this so that if multiple users need to use an application file/connect via application they can.

6) The 6th Layer of OSI is the Presentation layer. This layer is designed to handle data formatting differences between communicating computers.

The 6th layer of the OSI Model would need to be present in case there was a need to format some principal within a computer and its system.

7) The OSI Application layer is the 7th and final layer of the OSI Model. This is the layer that governs application-specific matters not covered by the OSI Presentation layer or the Session layer.

This layer we believe should be present in our network because it governs all the things that other layers will not.

Timeline GANTT Chart**Summary**

The bulk of labor considered in this project will be in the installation of network wiring between the buildings. About half of the project time will be devoted to simply waiting on the components and hardware. With the two budget options provided, your business will benefit according to its financial and productivity preferences. Our COST option provides an arguably acceptable cost while maintaining a quality network. Our recommendation of the EFFECTIVE option is pricey, and though it will run comparably to the COST option in high networking traffic, it consists of the high end servers needed to handle complex business processes and applications. With IBM supplying servers for both options, running the business's workspaces won't be difficult. Selecting an option that fits your workload and speed efficiency best is directly related to the server you will be using. IBM Blade servers are high-end and extremely reliable. Choosing the EFFECTIVE option will save you time and patience, as the products are much higher quality. The COST option will save you a significant amount of money but will need considerable maintenance attention and quite possibly product replacement.
